London, SW1, UK

Edited by

John L.Hollington
Smiths Industries/Aerospace
and Defence Systems Company
Bishop's Cleeve
Cheltenham Glos. GL52 4SF, UK

This compilation is taken from the large collection of material, including bound UK Patent
Abridgements, presented to the British Library by Mr Cousins and housed in the special
collections room at the Holborn Branch of the Science Reference and Information Service,
25 Southampton Buildings, Chancery Lane, WC2A 1AW, UK

THE MISSION OF AGARD

According to its Charter, the mission of AGARD is to bring together the leading personalities of the NATO nations in the fields of science and technology relating to aerospace for the following purposes:

- Recommending effective ways for the member nations to use their research and development capabilities for the common benefit of the NATO community;
- Providing scientific and technical advice and assistance to the Military Committee in the field of aerospace research and development (with particular regard to its military application);
- Continuously stimulating advances in the aerospace sciences relevant to strengthening the common defence posture;
- Improving the co-operation among member nations in aerospace research and development;
- Exchange of scientific and technical information;
- Providing assistance to member nations for the purpose of increasing their scientific and technical potential;
- Rendering scientific and technical assistance, as requested, to other NATO bodies and to member nations in connection with research and development problems in the aerospace field.

The highest authority within AGARD is the National Delegates Board consisting of officially appointed senior representatives from each member nation. The mission of AGARD is carried out through the Panels which are composed of experts appointed by the National Delegates, the Consultant and Exchange Programme and the Aerospace Applications Studies Programme. The results of AGARD work are reported to the member nations and the NATO Authorities through the AGARD series of publications of which this is one.

Participation in AGARD activities is by invitation only and is normally limited to citizens of the NATO nations.

The content of this publication has been reproduced
directly from material supplied by AGARD or the author.

FOREWORD

A literature survey on The Gyroscope and its Applications was compiled by Dr-Ing. Helmut Sorg and published in December 1970 (AGARD-Report-582). In a foreword to the report Professor C.T.Leondes stated that its purposes were to offer engineers and scientists a listing of books which were readily available, to broaden the knowledge and to prevent a duplication of research in the field of gyroscopes. That most useful report is a comprehensive list of all the books which may be readily consulted, but it includes nothing from the patent literature nor anything from the vast store of technical papers on the subject that are to be found in the learned journals of the world.

A complete survey of the whole subject is too large for any one man to tackle successfully.

In this new report, Mr Frank W.Cousins has worked for fourteen years in the great libraries of London and has produced a most scholarly work which makes great inroads into material, the whole of which would take several lifetimes to exhaust.

He thus carries on the work that Dr Sorg initiated with AGARD and reiterates the belief of Professor Leondes, that it will contribute to the broadening of human knowledge in this difficult, but fascinating subject. The report is in bibliographical form which implies that it is a symbol of a constantly-growing organism in a way more closely allied with the subject than any text can hope to be.

Eric R.Laithwaite
Emeritus Professor of Heavy Electrical Engineering
Imperial College, London

ACKNOWLEDGEMENTS

I wish to acknowledge my special debt to Mrs V.Tattle of The British Library who has given me generously of her skill over many years of research; the Trustees of the British Museum; The Controller of H.M. Stationery Office, The Comptroller General of Patents and The Commissioner of Patents and Trade Marks of the United States Department of Commerce.

I am further indebted to my friends Professor Eric Laithwaite, Mr Derek Lever and Mr Ralph Arnot for help and encouragement over more than a decade.

Many have given permission generously for me to reproduce photographs and other material. I wish especially to acknowledge the kindness of Dr Glyn Daniel of *Antiquity*; Joy Maggs of Sperry Ltd; The Director & Secretary of the Science Museum, London, The Teylers' Museum; Spaarne Haarlem, The Neils Bohr Library, Museum of the History of Science Oxford University; The Bodleian Library the Kunsthistorisches Museum, Vienna, the Plenum Publishing Corporation of New York, my friend Basil Minett now retired of British Aerospace and my friend M. Alain Brieux the distinguished historian of science for allowing me to show *inter alia* the gyroscopic transmission of our mutual acquaintance the late M. Bernard Salomon.

Finally I wish to thank Mr J.L.Hollington, Dr G.Beardmore and Mr D.S.Markham of Smiths Industries Aerospace & Defence Systems Ltd, also Lt Colonel P.Carré FAF; Lt Colonel A.Rocher and Professor Dr Ing. R.C.Onken of AGARD for their interest in and active support of my work.

Frank W.Cousins
Westminster 1987

PREFACE

The purpose of this report is to direct the student of the gyroscope and gyroscopic phenomena to that *terra incognita** of technical literature that resides primarily in the patent literature of Great Britain and the United States of America**, augmented by that which resides in the technical journals of each of those nations and those of the U.S.S.R. I have tried to review all of the British patent specifications, but I am well aware that there may be some lacunae.

I have not been able to extend my researches into a complete examination of the patent specifications of the United States of America, but where I do record them, and provided they have a number higher than No. 2415067 of c.1947, then each U.S. specification will itself provide a review of the related prior art. Hence each U.S. specification is itself a valuable reference to a much deeper field of enquiry. It is the same with the learned journals of the World, each paper will carry a useful bibliography and again the field of enquiry is remarkably extended thereby.

I have seen all of the entries I have made and I have given the names of the Journals in full to try to save the confusion that surrounds the present poor state of bibliography.

To produce this report has taken fourteen years of research, and I think I may be allowed to draw attention to that part that deals *inter alia* with gyroscopic gears. The subject has not previously appeared in any text on gear design, and is to be found, as far as I am aware, solely in the patent literature. I offer it here, for the first time to a wider audience.

Frank W.Cousins
Westminster. 1987.

* The term is not too extravagant since The British Library in London holds in excess of twenty two million patent specifications.

**The research has been primarily in British and American patent specifications and in consequence corresponding foreign patents may exist. The reader is directed to study the problem from Derwent Patent No. Family Index which began in c.1974.

L'objet du présent rapport est d'orienter l'étudiant du gyroscope et des phénomènes gyroscopiques vers cette "*terra incognita*"* de la littérature technique. Celle-ci se trouve principalement dans la documentation concernant les brevets en Grande Bretagne et aux Etats Unis** et dans les revues et journaux techniques de chacune de ces nations ainsi que de l'URSS. Je me suis imposé comme tâche de passer en revue toutes les spécifications de brevets britanniques, mais je suis conscient du fait qu'il pourrait y avoir des lacunes.

Je n'ai pas été en mesure d'élargir le domaine de mes recherches afin de présenter une revue exhaustive des spécifications de brevets des Etats-Unis, mais là où j'y fait référence — et pourvu qu'il lui soit attribuée un numero supérieur au No.2415067 du c.1947 — chaque spécification US fournira d'elle-même un aperçu de l'état de l'art pré-existant. Chaque spécification US sera donc de référence précieuse à une activité de recherche plus approfondie. Il en est de même pour la littérature savante du reste du monde, où chaque communication comporte des références bibliographiques de valeur, qui serviront aussi à élargir le champ des recherches de façon considérable.

J'ai examiné personnellement tous les documents inclus dans mon rapport et j'ai cité les noms des différentes revues en toutes lettres, en espérant ainsi éviter la confusion qui caractérise la situation actuelle médiocre de la bibliographie dans ce domaine.

Le présent rapport représente un travail de recherche de quatorze ans, et je pense qu'il me serait permis de signaler la partie qui traite *inter alia* des engrenages gyroscopiques.

Ce sujet ne paraît nulle part ailleurs dans les textes concernant la conception des engrenages, et à ma connaissance, il n'est traité que dans la littérature des brevets. Je le propose, pour la première fois, à un public plus large.

Frank W.Cousins
Westminster 1987

* Le terme n'est pas trop fort puisque la British Library de Londres contient plus de 22.000.000 spécifications de brevets.

**Nos recherches ont porté principalement sur les spécifications de brevets britanniques et américains, et par conséquent, il se peut qu'il existe des spécifications étrangères équivalentes. Nous attirons l'attention du lecteur sur le Derwent Patent No. Family Index, qui date de c.1974.

682525	760251	942060	1484793
683777	761521	960818	1506180
686362	777021	964763	1513770
706494	777818	1010343	
718124	798336	1051905	

10.13 G.B. Patent Specifications directed to Gyro Verticals erecting torques applied by magnetic effects

309150	517587	601447	660208
345127	545694	602235	671861
378148	547208	605955	732975
464193	549944	612608	740796
468288	592500	615734	756504
501945	593733	619939	798107
510524	601444	654041	

10.14 G.B. Patent Specifications directed to Gyro Verticals erecting torques applied by masses controlled by solenoids

173839
186655
584147
645332
834724
1065624

10.15 G.B. Patent Specifications directed to Gyro Verticals erecting torques applied by unclassified means

108677	211200	382343	847964
126395	261117	401039	856685

11. THE DIFFERENTIATING GYROSCOPE

(Gyroscopic spin-rate meter to determine angular velocity of rotation of a vehicle around any one of its main axes. In certain aircraft differentiating gyroscopes are used *inter alia* in yaw, pitch and roll. On certain satellites, differentiations gyroscopes can be used for damping oscillations with respect to its centre of mass).

12. THE INTEGRATING GYROSCOPE

The integrating gyroscope is a gyroscopic angular velocity integrator, used to determine the angle of rotation of an object by integrating the component of its angular velocity around the axis of measurement for use *inter alia* in auto pilots and navigational control systems.

*See Laithwaite E.R. iii (1975)

**This invention was demonstrated to the German Patent office in Munich on 30 April 1974 and was supported by a Statutory Declaration in support of its motion by Prof. E.R.Laithwaite dated 2 October 1973. The same device was seen to work by Mr G.K.C.Pardoe of Hawker Siddeley Dynamics Ltd and this is stated in a letter to the inventor of 14 Nov 1972. A subsequent Technical Note TN 3928 of 5 March 1973 by Hawker Siddeley Dynamics written by A.Smith attempts to show that the machine cannot work from a mathematical analysis.

26.3 A Review of the Mathematical Analyses listed previously

The mathematical investigations into the dynamics of an absolutely rigid body about a fixed point have been extensive, both in Europe and in the Soviet Union. In Europe we have the early work of Hess. W. (1890)* and that of the Russian mathematician Sofya Vasilievna Kovalevskaya (1850-1891)**.

Kovalevskaya formulated the statement of the existence of unique solutions of the problem of the rotation of a heavy body about a fixed point. Her classic work is well explained by Tabor, M. (1984) who shows that it concerned the solution of the Euler-Poisson equations that describe the motion of a top spinning about a fixed point. They are a set of six, first-order, nonlinearly coupled, ordinary differential equations of the form

$$\begin{aligned} A \frac{dp}{dt} &= (B - C)qr - \beta z_0 + \gamma y_0 & \frac{d\alpha}{dt} &= \beta r - \gamma q \\ B \frac{dq}{dt} &= (C - A)pr - \gamma x_0 + \alpha z_0 & \frac{d\beta}{dt} &= \gamma p - \alpha r \\ C \frac{dr}{dt} &= (A - B)pq - \alpha y_0 + \beta x_0 & \frac{d\gamma}{dt} &= \alpha q - \beta p \end{aligned}$$

where (p, q, r) and (α, β, γ) are the components of angular velocity and the direction cosines (that define the orientation of the top) respectively. The variables (A, B, C) and (x_0, y_0, z_0) are the moments of inertia and the position coordinates of the centre-of-gravity respectively. These are the adjustable parameters of the system — for different values of which the system may or may not be integrable.

The solving, or integrating, of such a system of equations proceeds by identifying the integrals of the motion — a complete integration requires one to find as many integrals as the order of the system (six in this case). These integrals are various analytical functions of the dependent variables that are constant in time. From fundamental physical considerations there are certain 'classical' integrals that can be identified immediately. These are the total energy, the angular momentum and, from simple geometric considerations, the sum $\alpha^2 + \beta^2 + \gamma^2$. As it turns out, with further standard simplifications, a complete solution of the problem requires the finding of only one more integral. The quest for this fourth integral became a popular problem in eighteenth and nineteenth century mathematics. However, it could only be found for three special cases: the trivial case of $A = B = C$, the case $x_0 = y_0 = z_0$ due to Euler and the case $A = B, x_0 = y_0 = 0$ due to Lagrange. A general solution to the problem, according to Tabor, seemed to be unobtainable.

The quest for the existence conditions of the fourth integral was finally solved *inter alia* by Poincaré J.H. c.1881. See Sergeev V.S. (1982), Painlevé P. (c.1891 to c.1900) Husson E. (1905) Burgatti P. (1906-1910) and Polubarinova-Kochina (1940). For a comprehensive work in English see Leimanis E. (1965).

Fradkin B.N. and Slyusarenko V.M. (1975)*, a translation of whose work is reproduced below, show that attempts have been made to obtain the equations that have the simplest form [17, 38, 39, 53, 86, 98, 103, 108]**. A result close to that expected had already been obtained by Hess [21] in the 19th century. Introducing new variables, Hess indicated a third-order system, which, however, also contained leading variables. The Hess equations are discussed in the monographs of A. Gray and V.V. Golubev [21] and the articles under the following references [129, 135, 141, 144, 145, 146].

N.Kowalewski's problem of 1908 [134] reduced to two equations, each of which is of the second order, under the assumption that the centre of mass of the body is found on one of its principal axes of inertia with respect to a fixed point. Using these equations, he succeeded in obtaining a new solution. Similar equations are presented in the manuscripts of S.A. Chaplygin [72], where the first integral of these equations is indicated, and the integrability case bearing his name is obtained, generalizing the solution of Goryachev [33].

Using the usual methods of analytical dynamics, Bilimovich [17] and Kharlamova [88] showed that the problem can be reduced to a single second-order differential equation; however, the latter can prove to be extremely cumbersome.

Kharlamov [110] proposed a new approach to the solution of this question. He noted that in the investigation of the problem of the motion of a heavy rigid body in a number of cases it is more convenient to refer the motion of the body to coordinate axes that the author calls special. The dynamic equations of the problem obtained by Kharlamov [103, 108] in the special coordinate system have the form

$$\begin{aligned} & [(a_2 - a_1)yz + (b_2y - b_1z)x^3] \left(y \frac{dz}{dx} - z \frac{dy}{dx} \right) + (y^2 + z^2)(b_1y + b_2z) \\ & + x \left[\left(a - \frac{a_1}{2} \right) y^2 + \left(a - \frac{a_2}{2} \right) z^2 \right] + \frac{a}{2}x^3 - Ex - k = 0; \quad (1.1) \\ & \left\{ [(a_2 - a_1)yz + (b_2y - b_1z)] \frac{dy}{dx} + (a_2 - a)xz - (b_1y + b_2z)z + b_2x^2 \right\}^2 \\ & + \left\{ [(a_1 - a_2)yz + (b_1z - b_2y)] \frac{dz}{dx} + (a_1 - a)xy - (b_1y + b_2z)y + b_1x^2 \right\}^2 \\ & + \left[\frac{1}{2}(ax^2 + a_1y^2 + a_2z^2) + (b_1y + b_2z)x - E \right]^2 - \Gamma^2 = 0. \end{aligned}$$

In these equations x, y , and z are the components of the angular momentum of a body in a rectangular special coordinate system, the first axis of which passes through the centre of mass of the body, and the remaining axes of which are chosen so that the kinetic energy of the body will be

$$T = \frac{1}{2}(ax^2 + a_1y^2 + a_2z^2) + (b_1y + b_2z)x.$$

Considering the problem of the motion of a heavy rigid body with a fixed point as a particular case of a more general problem — the problem of the motion of a heavy gyrostat with constant gyrostatic moment — Kharlamov [110] reduced the latter to the integration of a system of six ordinary differential equations,

**The numerals in square brackets refer to the bibliography at the end of this Review. The bibliography extends to 149 references, many in the translation published in 1975 are inaccurate and carry no pagination, further certain works are stated to be in Russian when in fact English translations exist. The bibliography in this section is fully corrected for readers of English.

$$A_2 = (E - C) qr + \lambda_2 r - \lambda_3 q + (l_1 v_3 - l_3 v_2) \Gamma \\ v_1 = rv_2, qv_3 (A, B, C, p, q, r, 1, 2, 3), \quad (1.2)$$

where λ_1 , λ_2 , and λ_3 are the components of the gyrostatic moment, constant with respect to the body.

This system of equations was transformed [108] to the form (1.1). Almost all the results of the classical problem of the motion of a heavy rigid body with a single fixed point were extended to the problem of the motion of a heavy gyrostat.

In the most general form of Kharlamova [90], one of the three principal variables x , y , and z was eliminated in Equations (1.1). However, the established differential equation, which connects the two principal variables, is extremely cumbersome, and is therefore practically useless. Of principal value is the integrodifferential equation first found by Kharlamova [86], which is equivalent to the system of differential equations of motion of a heavy rigid body about a fixed point. This equation opened many possibilities for further investigations in the given area. The equation of Kharlamova was obtained assuming that in the principal plane of the ellipsoid of gyration for a fixed point, there lies the centre of mass of the system and the vector of the gyrostatic moment. It connects the two components x and y of the angular momentum with respect to the coordinate axes belonging to the indicated plane.

Solutions Obtained in the 20th Century for the Equations of Motion of a Heavy Gyrostat.

We first distinguish the solution with three linear invariant relations, which was studied by Kharlamov [110, 112]. It determines the class of simplest motions of the body (uniform rotations of the body about a fixed point). A cone fixed in the body is indicated, and its generatrices can serve as axes of uniform rotation. This cone was thoroughly studied by Anchev [1, 2] and Kovalev [45], and in the absence of a gyrostatic moment it was investigated earlier by O.Shtaude and B.K.Mlodzevskii. This question has also been studied by other authors [62, 69, 70, 121, 133, 139, 149].

There exists a unique solution with two linear invariant relations given by Kharlamov [104, 109, 110], which was obtained under the condition that the centre of mass of the gyrostat lie in the principal plane of the inertia ellipsoid. The motion of the body so obtained is given a kinematic interpretation [107]. A particular case of the given solution is the Bobylev — Steklov solution (see the work of V.V.Golubev [21]) and the solution of the problem of the motion of a physical pendulum.

There are four well-known solutions with a single linear invariant relation; these are the solutions of Lagrange in 1738 see Grioli [128], Sretenskii [73, 74], and Kharlamova [89].

Sretenskii obtained the indicated solution by assuming that the centre of mass of the gyrostat is perpendicular to the circular cross section of the ellipsoid of gyration. A particular case of this solution is the solution of Hess, which was studied earlier by P.A.Nekrasov, S.A.Chaplygin, N.E.Zhukovskii (Joukowski), G.G.Appel et al. and B.K.Mlodzevskii. A complete review of these studies is given in the works of Stepanova [76, 77]. A geometrical interpretation of the solutions of L.N.Sretenskii and W.Hess was given by Kovalev [44, 46-53].

In 1947, Grioli [128] obtained a solution with a single linear invariant relation, describing the regular precession about an oblique axis. It was obtained and generalized by Kharlamova [89, 92]. In [92] the solution of Grioli was investigated on the basis of the kinematic equations of Kharlamov [110].

The question of the existence of solutions with linear invariant relations was first considered by S.A.Chaplygin, and the results were refined by Kharlamov [102]. These investigations were conducted under the condition that the centre of mass of the body lies in the principal plane of the ellipsoid of gyration, and that the gyrostatic moment equal zero. The investigation of the problem of the motion of a heavy rigid body about a fixed point with the help of the integrodifferential equation established by Kharlamova [86] allowed a complete solution to be obtained for the question of the conditions of existence for solutions with algebraic invariant relations under certain limiting assumptions: the centre of mass of the body lies in one of the principal planes of the ellipsoid of gyration, and the gyrostatic moment is not zero [91, 96]. In this case the new and most recent solution with a linear invariant relation is obtained [89]. Solutions [81, 83], found earlier by Kharlamova, are a particular case of this solution.

Goryachev indicated a solution [32] in which, in addition to a quadratic invariant relation, there is also a fourth-degree invariant relation. Kharlamov [110, 111] completely investigated this solution and gave a geometrical interpretation for the motion of the body. In studies [105, 110, 111] he indicated two more solutions. The first solution with two quadratic invariant relations was obtained under the condition that the centre of mass lies on one of the principal axes of inertia, and the vector of the hydrostatic moment is directed along this axis. The solution of Steklov [21] is a particular case of this solution. The second solution generalized the case of Kowalewski [134]. The indicated solutions are discussed in the studies [28, 29, 61, 65, 67, 99, 116].

Chaplygin in 1948 [129] obtained a solution in which, besides a quadratic invariant relation, there is also a sixth-degree algebraic invariant relation. The geometrical interpretation of this motion was given by Kharlamov [110].

A solution with a quadratic invariant relation was obtained by A.I.Dokshovich under the condition that in a Lagrange gyroscope the gyrostatic moment is arbitrary. The uniqueness of this solution was shown by Kharlamova [94].

We note three more solutions with a quadratic invariant relation. These are the solutions of Kharlamov [114], Kharlamova [36, 95], and Kharlamova and Kharlamov [110]. Particular questions referring to the given solutions are discussed in the studies [40, 41, 51, 97, 101, 115, 117].

The algebraic invariant relations in four solutions — those of Sretenskii [73, 74], Dokshevich [42], Mozalevskaya [62, 63], and Konzsevich and Pozdniakovich [54] — contain terms of higher degree. Thus, in the solution of [62] there exist two third-degree algebraic invariant relations, and in the solution of [42] there exist two fourth-degree algebraic invariant relations. The solution of [54] is very special in structure; it was investigated in [55] using the hodograph method. The indicated solutions were obtained for very strict constraints imposed on the mass distribution and on the initial conditions.

Thus, in the problem of the motion of a heavy gyrostat there exist twenty solutions in closed form, of which three of them had been found in the 18th and 19th centuries (we bear in mind the solution of L. Euler, generalized by N.E. Zhukovskii (Joukowski), the solution of J. Lagrange and S.V. Kowalewski as discussed by L.V. Kudryashova and L.A. Stepanova in [58] and by G.N. Savin et al in [71]).

A review of the exact solutions of the dynamic equations of the problem being considered was given by Kudryashova and Stepanova [55].

Geometrical Interpretation of the Motion of a Rigid Body about a Fixed Point.

For a long time the general theorem of Poinsot about the interpretation of the motion of a body with a fixed point by means of the rolling without slipping of a moving axoid with respect to a fixed axoid was not used because the construction of a fixed axoid using the Euler angles is a very complicated problem; this is because in the transformation from a moving system to a fixed system in these parameters we obtain cumbersome and nonsymmetric expressions which hinder the investigation of the motion of the body. This impasse was overcome by Kharlamov [108, 110], who established new kinematic equations of the fixed hodograph of the angular velocity.

$$\omega_3 = \omega_1 v_1 + \omega_2 v_2 + \omega_3 v_3; \quad \omega_p^1 = \omega_1^2 = \omega_2^2 + \omega_3^2 - \omega_1^2;$$

$$\omega_p^2 d\alpha = \begin{vmatrix} v_1 & v_2 & v_3 \\ \omega_1 & \omega_2 & \omega_3 \\ dv_1 & dv_2 & dv_3 \end{vmatrix}$$

(ω and v are functions of some time-dependent parameter α).

Since it is the directrix of the axoid of the body, the hodograph of the angular velocity enables us to construct this cone and to reduce the investigation of the motion of a rigid body with a fixed point to the motion of the rolling of a moving axoid with respect to a fixed axoid. Using this method, a geometrical interpretation of the motion of a gyrostat in various cases of integrability is obtained in the studies [24, 26, 29-31, 46, 48-50, 51, 55, 61, 63-65, 87, 99, 110, 111, 116, 117].

Motion of a Rigid Body with a Fixed Point in a Potential Force Field.

First, we should note the studies of Goryachev [34-36], in which solutions are constructed for the problem of the motion of a body in a potential force field under the condition that the forces acting on the body admit a force function U . The question dealing with the search for the function U , in such a form that the equations of motion admit integrals of definite form, is solved. A detailed review of these solutions has been given by Stepanova [75].

In recent years, there has been increased interest in the problem of the motion of a rigid body in a Newtonian force field, formulated by L. Euler back in the 18th Century, in connection with investigations of the motions of artificial satellites. In calculations of the rotational motions of gyroscopes and satellites, the gravitational field almost always is assumed to be homogeneous. This assumption is inadmissible in more exact investigations in which the forces of Newtonian attraction must be taken into account.

Bel'tskii [12-14] has considered this problem under the assumption that a fixed point is found at a sufficiently large distance, in comparison with the dimensions of the body, from the centre of attraction. Under these conditions on the basis of the general theory of Goryachev [34], approximate equations of motion, which generalize the equations of the classical problem of the motion of a heavy rigid body about a fixed point, are derived. Bel'tskii has shown that the problem being considered is finally solved if the body has complete kinetic symmetry, and also in cases similar to the cases of Euler and Lagrange. He has reduced the problem to quadratures and given its complete solution for the case of plane motion. In [13-15] he has considered the indicated problem for the case in which the force field is symmetric with respect to some axis.

A series of studies by Arkhangelskii [6-10] referring to the indicated problem are devoted to the determination of the conditions for existence of a fourth algebraic integral and the construction of solutions in which the principal parameters are single-valued functions of the complex variable t . In these studies it is shown that the solutions of the equations of motion of the body are single-valued functions of time only if the body is fixed at the centre of mass or has dynamic symmetry about one of the principal axes of inertia, and the centre of mass of the body lies on this axis.

Important results in the development of the given problem have been obtained by Kharlamova and Koroleva [98], who constructed dynamic equations of the problem of the motion in a Newtonian force field of a system of rigid bodies having the structure of a gyrostat:

$$\begin{aligned}
 A_1\omega_1 + (A_1 - A_2)\omega_2\omega_3 + \lambda_3\omega_3 &= (I_2v_3 - I_3v_2)\Gamma + \\
 + \varepsilon^2 A_{33}^*v_2 + A_1^*v_1 + A_{32}^*v_2) v_2 - (A_{22}^*v_1 + A_{23}^*v_3 + A_{31}^*v_1) v_3], \\
 v_i = \omega_3v_2 - \omega_2v_3 (1, 2, 3).
 \end{aligned} \tag{2.1}$$

For the condition in which the tensors \tilde{A} and \tilde{A}^* that arise in the calculation of the angular momentum and the moment of the Newtonian force field coincide and the hydrostatic moment equals zero, these equations are simplified:

$$A_1\omega_1 = (A_2 - A_3)(\omega_2\omega_3 - \varepsilon^2 v_2 v_3) + (I_2v_3 - I_3v_2)\Gamma, \quad v_i = \omega_3v_2 - \omega_2v_3 (1, 2, 3).$$

For the condition in which the tensors \tilde{A} and \tilde{A}^* coincide, Kharlamova [85] obtained exact solutions of system (2.1), similar to the case of Lagrange integrability at the problem of the motion of a physical pendulum. She determined a new case of integrability for the conditions

$$I_1 = 0, \lambda_1 = 0, A = B + C, B^2 I_2^2 + C^2 I_3^2, \varepsilon^2 = (B^2 I_2^2 + C^2 I_3^2)\Gamma.$$

Kovaleva [52] solved the question of the conditions of existence of the solutions of system (2.1) with linear invariant relations.

In the case of the establishment of definite constraints on the parameters of the system in the solution of Kharlamova [85], Gor' [22, 23, 25, 27] investigated moving and fixed hodographs of the angular velocity and gave a geometrical interpretation for the motion of the body.

Some of the studies of Kharlamova [82, 84] are devoted to the construction of exact solutions of system (2.2). A complete review of these investigations is given in the article by Kudryashova and Stepanova [57].

Motion of a Rigid Body about a Fixed Point in the Presence of Additional Constraints

The first attempt on the formulation of the problem of the rotation of a rigid body about a fixed point in the Euler case in the presence of nonholonomic coupling was conducted by Suslov [78], Voronets [19], and Vagner [18], who did not impose any constraints on the moments of inertia of the body, but assumed that the centre of mass of the body coincides with the fixed point.

Realization of the nonholonomic constraint $\omega_3 = 0$ Suslov is carried out such that the body is connected to a filament, which does not yield under torsion; the other end of the filament is rigidly fixed, where the tangent to the filament at the point at which the filament is fastened to the body passes through a fixed point 0. Under this condition the instantaneous axis of rotation of the body is in a plane that is permanently coupled with the body, passing through the point 0 perpendicular to the indicated tangent.

Vagner proposed another realization of a nonholonomic constraint (a rigid body provided with two small wheels with sharp ribs lying in a single plane).

Recently, a number of studies [43, 66, 79, 80, 93, 115, 118] have appeared, which are devoted to the study of problems of the motion of a heavy rigid body with a fixed point in the presence of additional constraints.

The principal results in this direction were obtained in the studies of Kharlamov, Kharlamova née Zabelina, and Mozalevskaya [43, 61–67, 80, 91, 115, 118].

In 1957, Zabelina [43] investigated the indicated problem under the condition that the centre of mass of the body be found in the principal plane of the inertia ellipsoid with respect to its point of support, not coinciding with the fixed point of the body, and with account of the action of gravitational forces. The nonholonomic constraint in this investigation can be realized either based on the method of Suslov or the method of Vagner. The case of integrability is found by applying the theory of the reducing factor of Chaplygin, which he developed for an investigation of nonholonomic systems.

In the study of Kharlamova-Zabelina [80], a nonholonomic constraint is assumed to be realized such that the instantaneous axis of rotation of the body throughout the entire motion does not leave some specific plane permanently fixed in the body. Using a method proposed by Strelenskii, Kharlamova-Zabelina considers the case of rapid rotation of a body and presents a detailed investigation of the trajectory of the apex, which enables one to construct an explicit geometrical representation dealing with the motion of the body for the given nonholonomic constraint.

The problem of the rotation of a rigid body about a fixed point restrained by a nonholonomic constraint can be extended to the case of a heavy gyrostat. Such an extension was obtained by Kharlamov and Kovaleva [115]. The nonholonomic constraint here is accomplished as a result of pure rolling of a body-carrier having a fixed point and sharp circular ribs over a fixed surface of a hollow sphere inside of which the gyrostat is placed. Using the theorem of the variation of the kinetic moment, the author constructs dynamic equations of motion of the gyrostat to which the equation of nonholonomic constraint is added. These equations are easily solved in the simplest case of uniform rotation of a body-carrier.

The problem of the motion of a heavy gyrostat is investigated by Kharlamova [93] under the assumption that the centre of mass of the gyrostat coincides with the fixed point of the body-carrier. An exact solution is obtained and the moving hodograph of the angular velocity of the body is investigated. The case investigated by Vagner [18] and earlier by Suslov [78] is a particular case of the indicated solution. In reference [118] a solution of this problem with an invariant relation that is linear with respect to ω_1 and ω_2 is given. This solution is a generalization of a number of known solutions of the indicated problem, found earlier by Bol'ychev and Steklov [21], and Kharlamova/Zabelina [43, 80]. As was determined by Mozaikovskaya [66], the solution with a linear invariant relation that was found by Kharlamov and Kharlamova in [118] is the only solution of this kind.

A review of studies of the problem being considered in the presence of nonholonomic coupling is given in references [59 and 71].

(in Russian) Mekhanika Tverdogo Tela (1974) No. 7 pp.59-82 Note: In connection with recently published assertions to the effect that D'Alembert was the first to formulate the fundamental equations for the dynamics of a rigid body, D'Alembert's work relating to the derivation of these equations is examined in conjunction with Euler's. It is concluded that the fundamental concepts of rigid dynamics were in the main first made explicit by Euler in a series of works from 1749 to 1767 (17 refs.)

*In the British Museum entries see KRILOV, A.N.
- Note:
Krylov investigated the general case of the motion of a ship when its course lies at any given angle to the direction of the waves, and summed up his conclusions in a paper entitled "General Theory of the Oscillations of a Ship on Waves", which was also published in English and French. Here he followed the same path he had outlined in his previous work, making all the necessary changes in setting up the differential equations of the motion of the body of the ship, whose position now had to be defined by all six parameters (three coordinates of the centre of gravity and three Euler angles). This led to increasing the number of equations to be integrated. The new problem did not raise any particularly difficult new questions, and in his work "On Stresses Experienced by a Ship in a Seaway", published by the Institute of Naval Architects in London, Krylov presents a computation of the strains set up in a ship in this more complicated case. These classic works placed Krylov in the first rank of world authorities on the theory of ships. The Society of English Shipbuilding Engineers awarded him the gold medal of the

Society, an honour bestowed on no foreigner before him. Such works as those mentioned above and his work in the theory of rolling stabilizers, Schlick gyroscopic stabilizers and Fram cisterns won recognition everywhere. Krylov was entrusted with writing the chapter on the theory of ships in the great encyclopedia of mathematical sciences, begun prior to World War I under the supervision of the famous mathematician Klein. The compilers of the encyclopedia set themselves the task, as Boltzman said, of finding the leading specialists in each field to draw up the various articles. Krylov's works are studied all over the world and are a guide to shipbuilding. In 1942 he was elected an honorary member of the Society of English Shipbuilding Engineers.

Note: This work explains what is often termed the Magnus effect. The moments of inertia of the suspension influence the movements of nutation of gyroscopes with cardan bearing. At a symmetrical gyro rotor they lead — as is already known — even at a bearing without any friction to a deviation from the middle direction of the axe under the influence of the movements of nutation; at an unsymmetrical gyroscope they influence the conditions of stability. In the present article both effects are examined in dependence on the oblique position of the inner cardan ring.

*This important paper is referred to by RIVKIN, S.S. It is not translated into English, as far as I am aware, but a note in English appears at the end of the Russian work. English translation of the Russian title of a work in Russian

Recent years have seen the ever-greater application of multi-gyroscopic systems in instruments designed to maintain horizontal planes in moving ships. The value of the employment of such systems was pointed out in the work by Krylov entitled General theory of gyroscopes and some technical applications of them. Krylov points out (page 265) that stabilization of platforms on a ship may be attained by the following means: the platform is suspended within a knuckle joint being attached to its internal ring. Attached to the platform are two gyroscopic stabilizers, one of which nullifies roll, the other pitch. The present paper is devoted to an investigation of the above outlined idea. In paragraph 1, the author gives a brief description of multi-gyroscopic verticals. Paragraph 2 gives differential equations for the motion of the instrument. Paragraph 3 discusses the motion of the instrument on a fixed support. Paragraphs 4 and 5 take up the influence of rolling and acceleration of the moving ship. Here it is established that the data yielded by a multi-gyroscopic vertical are much more precise in rolling than the data yielded by a single gyroscope. Paragraph 6 studies the motion of a multi-gyroscopic vertical with a free oscillation period equal to the period pointed out by M. Schuler $T = 84.4$ minutes. Paragraph 7 is devoted to the increase of error in gyroverticals for extended manoeuvring of the ship. The 9th and last paragraph discusses ballistic deviation of multi-gyroscopic verticals with a small free oscillation period. The author's gratitude is due to the B.V. Bulgakov, whose methods were used throughout in the present work and who gave the author much valuable advice.

- Verbrugge, F. *A dynamic model of magnetic resonance phenomena*
American Journal of Physics 21 (1953) pp.603-607 Note: A dynamic model to illustrate atomic and nuclear magnetic phenomena is described. An air-driven spinning magnetic dipole placed in a magnetic field exhibits a Larmor precession whose dependence on magnetic and gravitational parameters can be demonstrated. An ac magnetic field of variable frequency permits a visual demonstration of magnetic resonance. Data obtained from the precession experiments can be used for a precise determination of the Earth's magnetic field.

	AGARD-AG-313	ISBN 92-835-0441-0	UNCLASSIFIED
5. Originator	Advisory Group for Aerospace Research and Development North Atlantic Treaty Organization 7 rue Ancelle, 92200 Neuilly sur Seine, France		
6. Title	THE ANATOMY OF THE GYROSCOPE (A Report in Three Parts Comprising a Literature and Patent Survey Directed to the Gyroscope and its Applications)		
7. Presented at			
8. Author(s)/Editor(s)	Frank W.Cousins, edited by John L.Hollington		9. Date
10. Author's/Editor's Address	Various		11. Pages
12. Distribution Statement	This document is distributed in accordance with AGARD policies and regulations, which are outlined on the Outside Back Covers of all AGARD publications.		
13. Keywords/Descriptors	<p>Gyroscope, Navigation, Stabilisation,</p> <p>Coriolis effects, Gyroscopic forces, Tops, and NATO F-EN-SHE, (RKH) 4</p>		
14. Abstract	<p>This report on the gyroscope and its applications collates the technical information to be found in the patent literature, augmented by that residing in the text books and technical journals. The report is in three parts; Part I is a patent survey arranged in a detailed classification, Part II comprises a bibliography of the references in Part I and Part III, published as a separate volume, gives historical notes and comments on the material of Parts I & II.</p> <p>This AGARDograph has been prepared and edited at the request of the Guidance and Control Panel of AGARD.</p> <p>Keywords included</p>		

AGARDograph No.313 Advisory Group for Aerospace Research and Development, NATO THE ANATOMY OF THE GYROSCOPE (A Report in Three Parts Comprising a Literature and Patent Survey Directed to the Gyroscope and its Applications) by Frank W.Cousins, edited by John L.Hollington Published February 1988 296 pages	AGARD-AG-313 Gyroscope Navigation Stabilisation Coriolis effects Gyroscopic forces Tops	AGARDograph No.313 Advisory Group for Aerospace Research and Development, NATO THE ANATOMY OF THE GYROSCOPE (A Report in Three Parts Comprising a Literature and Patent Survey Directed to the Gyroscope and its Applications) by Frank W.Cousins, edited by John L.Hollington Published February 1988 296 pages	AGARD-AG-313 Gyroscope Navigation Stabilisation Coriolis effects Gyroscopic forces Tops
This report on the gyroscope and its applications collates the technical information to be found in the patent literature, augmented by that residing in the text books and technical journals. The report is in three parts; Part I is a patent survey arranged in a detailed classification, Part II comprises a bibliography of the references in Part I and P.T.O.		This report on the gyroscope and its applications collates the technical information to be found in the patent literature, augmented by that residing in the text books and technical journals. The report is in three parts; Part I is a patent survey arranged in a detailed classification, Part II comprises a bibliography of the references in Part I and P.T.O.

SUPPLEMENTARY

INFORMATION

*Part I
A197162*

PD

ADDENDUM AND ERRATA (to Parts I and II)

Part I.P.47. Under 13.35 Cryogenic Gyroscopes insert European Patent Specification 0297059

Part I.P.112. For 2585**6 read 2585886 (bottom right hand column)

~~Part II. P.112. For Derek Leaver read Derek J. Leaver.~~

ERRATA
